PHOTOELECTRIC OBSERVATIONS OF VW CEP IN 1950, 1952 AND 1959

by

JULIA BALÁZS AND L. DETRE

Over seven hundred white, blue and yellow observations were secured on 10 nights in 1950, 1952 and 1959 by Dr. I. Ozsváth and the writers. A review of all available photoelectric data confirms the relations found by Dr. Kwee between the light-curve variations and the phase-shifts of the minima, but the phenomena seem to be not periodic.

In 1950 and 1952 Dr. *I. Ozsváth* and the writers obtained about 500 photoelectric observations of VW Cep at the Newtonian focus of our 24-inch reflector using an RCA 931 A multiplier. At the beginning of the observations no colour-filters were used, later the observations were obtained through filters Schott BG 12 and GG 11. Shortly before the beginning of the international campaign in 1959 some observations were secured by the first writer in blue and yellow through filters BG 12 + GG 13 and GG 11 respectively, using an RCA 1P21 phototube. In all these observations the comparison star used was BD + 74°877 which was supected of variability by *R. S. Dugan* [1]. But apparently this star shows slow variations only, hence the observations on one and the same night are not effected by the variability of this star. In this way exact data can be obtained for the epochs of the minima and for the relative brightnesses of the maxima. These data are especially important for the study of the Kwee-effect [2]. Table I gives a summary of our observations. The magnitudes obtained for VW Cep are inserted in Tables III—V.

Together with the observations by *K. K. Kwee* [3], *K. Kostylev* [4], *McNamara* and *Stern* [5], *A. Szczepanowska* [6], *H. Schmidt* and *K. W. Schrick* [7] we have now a continuous series of photoelectric observations from 1948 to 1953. The epochs of the minima deduced from these observations together with the epochs obtained in 1959 are collected in Table II. The numbering of the epochs and the values $O - C$ for minima I and those of $O - C - 0.5\,P$ for minima II are according to the elements used by Kwee [14]:

$$\text{Min I} = \text{hel. J.D. } 2433898.4410 + 0^{d}.27831793.\,E$$

The epochs have been newly determined by us when the individual observations were at our disposal. Some observations are of low accuracy and the epochs in Table II may differ several minutes from those given in the literature. For

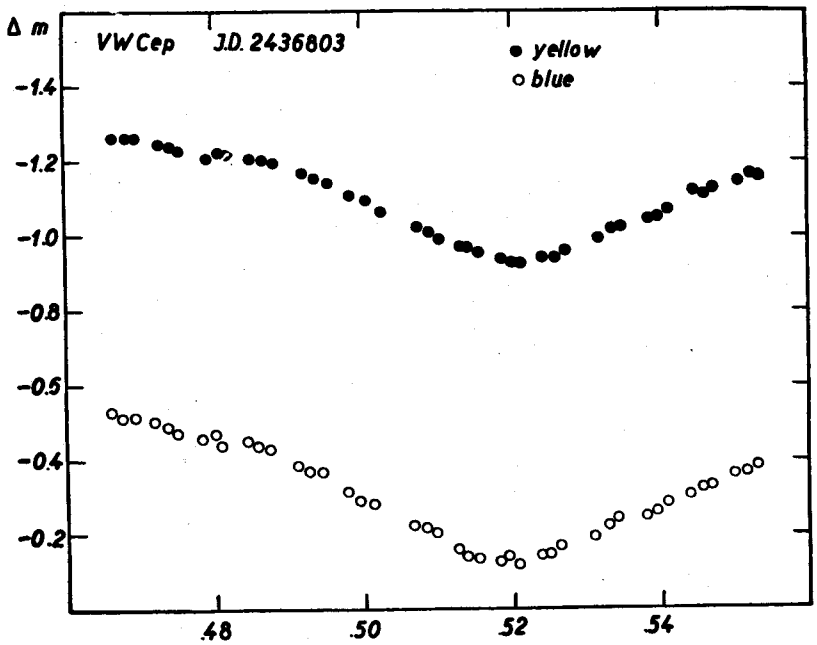

Fig. 4. Light-curves of VW Cep observed at Budapest on J.D. 2436803

Szczepanowska's observations we have deduced new epochs using the branches of the minima, whereas Szczepanowska used the moment belonging to the lowest value of the brightness as the epoch of the minimum.

Table I

Observations obtained at Budapest

Day	J. D. 243....	Time-interval	Number of observ. B	Y	W	Observer	Notes

Notes : 1. Sky very good. 2. Interrupted by clouds. 3. From .449 to .498 interrupted by clouds. 4. Sky unsteady. 20 observations in yellow and 22 observations in blue disregarded. 5. Observations after .440 interfered by clouds. 6. Between .401 and .508 interrupted by clouds.

Abbreviations : B for *Balázs, D* for *Detre, O* for *Ozsváth ; B :* blue, *Y :* yellow *W :* white.

The values of $O - C$ and $O - C - 0.5\ P$ respectively from Table II. together with those given by *Kwee* in Circular No. 5. of the Coordination Programme 1959, have been plotted in Figure 1. The diagram clearly shows the variations of the epochs of the minima, first announced by *Kwee*. The epochs of minimum II showed the same variations as minimum I, however with opposite sign: when minimum I was too late, minimum II was too early. *Kwee* supposed a periodicity of about 2 years for these variations, but according to Fig. 1. different cycles are of unequal length and amplitude. Further the values of $O - C - 0.5\ P$ for minimum II are on the average smaller than the values of $O - C$ for minimum I, the difference being about $0^d.002$. Therefore the phase difference of the epochs Min II — Min I is mostly smaller than 0.5.

According to *Kwee* the variations of the epochs of the minima are correlated with the variations of the brightnesses of the maxima. When the maximum preceding Min I (Max II) is the brighter one the epoch of Min I occurs later. The reverse is true when the maximum following Min I (Max I) is the brighter one. In accordance with this we have found Max I brighter than Max II for E = +10348 (Figure 3). Max II was found brighter than Max I by *Kostylev* ($E = -3931$), *Mc Namara* ($E = -2639$), by us ($E = -1290$), by *Kwee* ($E = +122$), *Szafraniec* ($E \sim 7300$). An infrared light-curve obtained by Hardie on 24/25 and 25/26 July 1951 ($E \sim -200$) shows also Max II as the brighter one [15]. The only contradiction to *Kwee*'s relation is *Mc Namara*'s light-curve, showing Max II as the brighter one although Min I was early. The complete cycle observed by Dr. *Ozsváth* on J. D. 2434303 ($E = +1455$) shows two equal maxima in yellow light (Figure 2) at a time when Max I
