U,B,V PHOTOMETRY OF THE MULTIPLE PERIODIC RR LYRAE STAR  
RV URSAE MAIORIS

SUMMARY

Three-colour photoelectric photometry of the  $RR_{ab}$  variable star RV Ursae Maioris, is presented. Period and total light curve changes of the star during the Blazhko period and O-C diagrams of both the main and the secondary periods are investigated. It was found that a certain phase point /  $\phi_s=0,94$  / of the ascending branches of the light curves showed no oscillation during the Blazhko period, which is hardly compatible with the assumption of the superposition of beat periods. A long cycle of 6-8 years in the O-C variations of the ascending branch was also found. Similar long cycle variations are shown by other RR Lyrae stars exhibiting the Blazhko effect, this variation being reminiscent of the solar magnetic cycle.

## INTRODUCTION

RV Ursae Maioris is an RRab Lyrae variable star whose light variation was among the firsts discovered. The variability of RV UMa was announced by Cerasky in 1907 /Cerasky 1907/, and its light elements were derived by Blazhko /1908/. According to the properties of the observed light curve and the period  $P=0^d.4684$  Blazhko classified the star as a short periodic  $\delta$ Ceph variable. In 1920, Jordan and Subbotin pointed out independently the strong variation of the light curve of RV UMa /Jordan, 1920; Subbotin, 1927/

Photographic observations of RV UMa were initiated at the Konkoly Observatory by Julia Balázs and Detre with a 16 cm astrograph in 1936. A great number of observations were made in Budapest confirming the existence of a Blazhko effect, however, the secondary period could not be determined until photoelectric observations were made by Balázs and Detre in 1956-1957. Using all published observations they derived for the secondary period  $P_s=90^d.8$ . They constructed O-C diagrams for both the fundamental and the secondary period over a time interval of 50 years.

According to Preston the spectral type of RV UMa at minimum light is F4 from H-lines and A6 from the Call-line giving  $\Delta S=8$  /Preston, 1959/. On 34 nights in 1959 and 1960 Preston obtained a total of 113 spectrograms of the star; with the X-spectrograph of the Mount Wilson 60-inch reflector concurrently Spinrad carried out photoelectric observations on the UBV system with the 20-inch reflector of the Leushner Observatory in Berkeley. In addition four light rises were observed by Preston with the 60-inch reflector in 1960. They used these series of photoelectric and spectroscopic observations to point out some peculiarities in the 90-day cycle /Preston and Spinrad, 1967/.

## THE PHOTOELECTRIC OBSERVATIONS

The present author observed RV UMa photoelectrically during the period 1961-1969, at first in yellow and blue, later also in ultraviolet light. Additional measurements were obtained by Csank, Gefferth and Lovas on the B, V system in 1958-59. The observations ranged over all phases of the primary and

secondary periods. In this way it was possible to study the variations of complete light- and colour-curves in the 90-day cycle.

The distribution of the observations is listed in Table I.

Table I

Year	Number of nights	Number of observations			Total
		Yellow	Blune	Ultra-violet	
1958	6	69	69	-	138
1959	10	138	138	-	276
1976	50	1356	1356	-	2712
1962	47	593	593	562	1748
1963	17	26	275	275	576
1964	15	110	110	110	330
1965	1	16	16	-	32
1968	2	33	33	14	80
1969	2	37	37	-	74
Total	150	2378	2627	961	5966

All observations were made with the 24-inch reflector of the Konkoly Observatory. The unrefrigerated photometer employed was equipped with an RCA 1P21 photomultiplier up to 1961, after that time with an EMI 9502B phototube.

The following filters were used

Colour	Type	$\lambda_{\text{eff}}$
yellow	Schott GG 11	5600 Å
blue	" BG 12+GG 13	4300 Å
ultraviolet	" UG 1	3950 Å

The photomultiplier output was amplified by a d.c. amplifier. The linearity of the instrument seemed to be warranted within the measuring interval.

The comparison star for our observations was the visual double star BD+55°1616. Spinrad used the same comparison star while BD + 54° 1610, used by Preston as a comparison star, was chosen as the check star. Both stars are within 20' to the variable. The photoelectric data for these stars were adopted from the measurements of Preston and Spinrad /Table II/.

Table II

	V	B-V	U - B
BD+55°1616	9.963	+ 0.507	- 0.114
BD+54°1610	9.62	+ 0.580	+ 0.095

Observations of standard stars published by Johnson and Morgan /1953/ were used to transfer the differential magnitudes and colours from the instrumental system u, b, v to the international U, B, V system by the formulae:

$$\begin{aligned} \Delta V &= \Delta v + \Delta/B-V/ /1/ \\ \Delta/B-V/ &= \mu \Delta/b-v/ /2/ \\ \Delta/U-B/ &= \phi \Delta/u-b/ /3/ \end{aligned}$$

The values of the coefficients were determined from time to time, though not frequently enough to be able to trace small variations caused by variability of sky transparency. Therefore, only the most significant variations of the coefficients were taken into account - specially that due to a transition from a silvered mirror to an aluminized one in 1961. Beginning with 1963 we have obtained sufficient data for the coefficients. The different sets of these coefficients are given in Table III, while the reduced observations are listed in Table IV.

Table III

Time interval		$\epsilon$	$\mu$	$\psi$
From feb.	1958			
to May	1963	- 0,132	1,05	1,08
	1964	- 0,14	1,12	1,16

January	1969	- 0,130	1,194	1,02
May	1969	- 0,177	1,181	0,955

## LIGHT - CURVE VARIATIONS

The main purpose of this investigation was to study the variations of the light curve in V and the B-V and U-B colour curves in the 90-day cycle for all phases  $\psi$  of the  $0,468^d$  period. However the observations were concentrated on the phases  $\psi = 0,85 - 0,05$ , i. e. on the minimum ascending branch and maximum of the light curve. Some individual V, B-V and U-B curves for these phases are represented in Fig. 1. To obtain complete light curves for all phases /the phase of highest maximum being taken as  $\psi=0/$  of the  $90^d$  secondary period the same procedure was applied as by Julia Balázs and Detre /1939/ for AR Herculis. From the observed light curves the magnitudes were read off for a set of  $\psi$ -phases and these magnitudes were then plotted versus  $\psi$ . In this way we obtained a sequence of curves representing the variation in the light curve for definite  $\psi$ -phases as a function of  $\psi$ .

For derivation of proper  $\psi$  and  $\psi$ -values the O-C diagrams must first be constructed for both the fundamental and secondary period. For C, the elements of Balázs and Detre /1957/ were used, viz.

$$/J.D. /maximum light/ = 2417861, 4292+0,468063203 E /I/$$

and

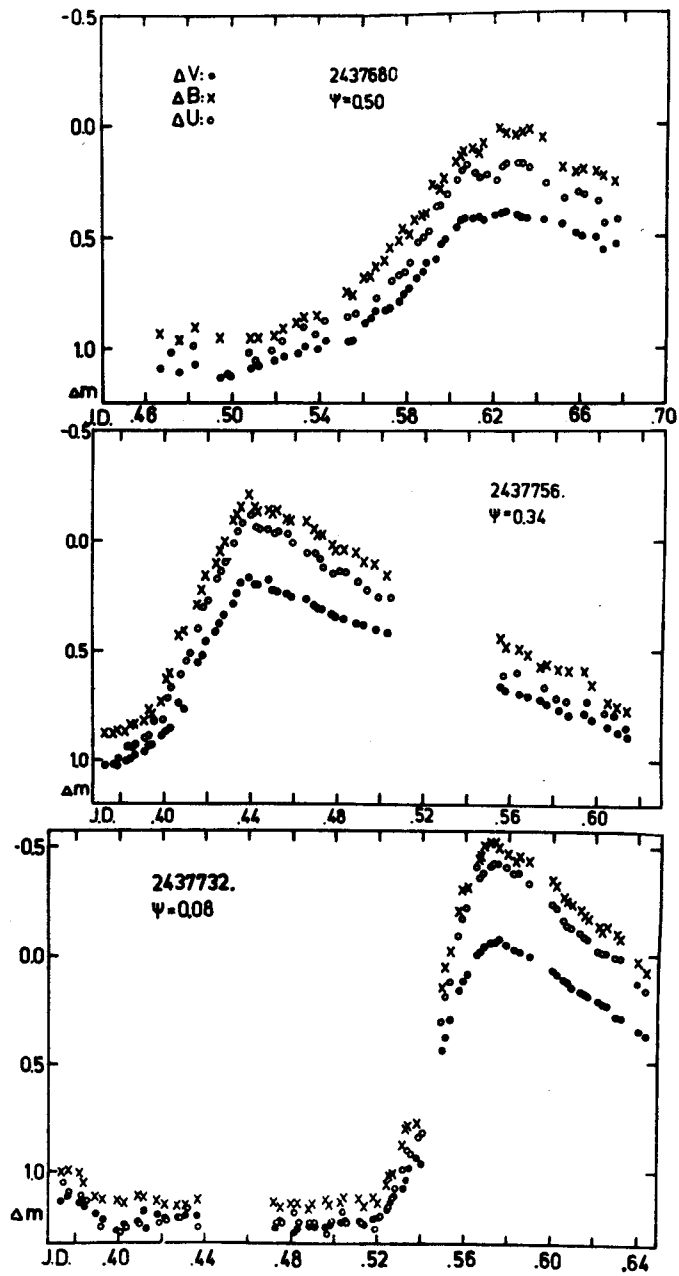

Figure 1 The observed light curves in UBV according to different phase points of Blazhko period.

J. D. /brightest maximum/ = 2418060 + 90,12 x N. /II/ where E and N are epoch counts in the respective periods. For each year the actual fundamental and secondary periods were determined by using the O-C /I/ and O-C /II/ curves. For instance the fundamental period obtained for 1961 /when the greatest number of observations were collected/ was

$$P = 2437327,692 + 0,468061103 \cdot E$$

and the secondary period

$$P_s = 2437359 + 92,12 \cdot N.$$

The brightest maxima were chosen from every observational season and are given in Table V. The O-C diagrams constructed for these maxima are shown in Fig 2. They are typical for RR Lyrae stars having a secondary period and their structure can be considered as resulting from the cumulative effects of random period changes. Even so, the comparison of O-C/II/ reveals two important characteristics:

1. The long cycles resulting from cumulative effects of random period changes are opposite in phase in the two diagrams. That is a change in the secondary period is accompanied by an opposite change in the fundamental period.

2. The changes expressed in units of the respective period are much larger for the secondary period than for the main one. These characteristics are especially conspicuous for RW Draconis and in some respect also for RR Lyrae /see Detre, 1970/. They are considered to be of fundamental importance for the interpretation of the secondary period.

A few  $V = V / \psi / \varphi = \text{const}$  - diagrams are represented in Fig. 3a. The scatter in  $V$  is largely due to the random variations in the periods which makes an exact determination of  $\varphi$  and  $\psi$  impossible. This is proved by the fact that the scatter is largest in the ascending branch, between phases  $\varphi = 0,85$  to  $0,975$ , which part of the light curve is especially sensitive to random phase variations.

Figure 3a

Figure 3

Similar marks on the diagram represent a certain  $\phi$  phase value of the fundamental period obtained from the light curves of different Blazhko phase  $\phi$ . Figures 3a, b, c are in  $\Delta V$ ,  $\Delta B$  and  $\Delta U$  respectively.

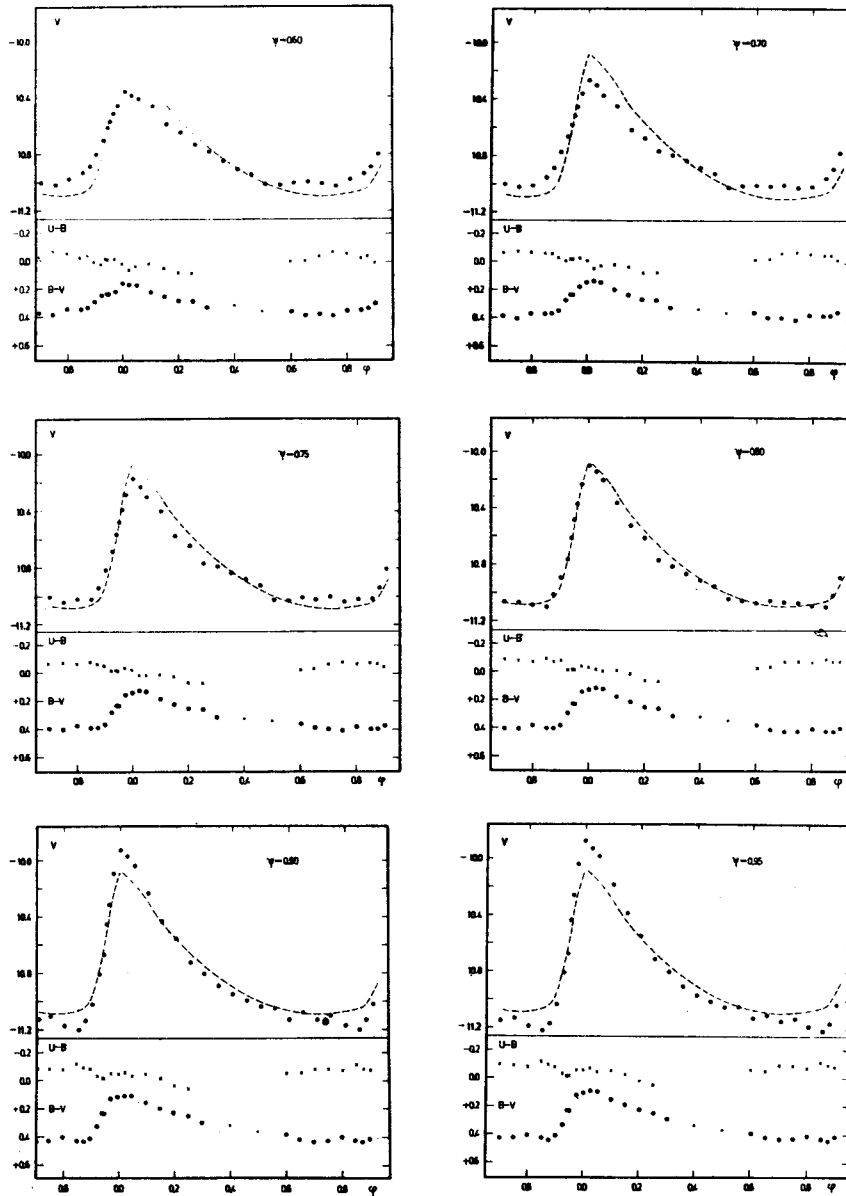

Figure 4  
The diagram shows the flattened light curves of different secondary period phase  $\phi$  constructed from figures 3a,b,c.

The same procedure was carried out in B and U, as well /Fig. 3b, 3c/ Using these curves the  $V / \varphi / \psi = \text{const}$ ,  $B-V / \varphi / \psi = \text{const}$  and  $U-B / \varphi / \psi = \text{const}$  diagrams /Figs. 4a and b/ were constructed on which all the following discussions are based.

The two-colour diagrams at different phases of the secondary period are shown in Fig. 5. On the loops the phases of the main period are also indicated. The dashed line is the relation for the main sequence stars.

The V magnitudes and B-V colour indices at minimum light and maximum light and the U-B ranges  $\delta_2$  / defined by Preston, Ann. Rev. of Astr. and Astroph. Vol. 2, 1964 / are plotted versus  $\psi$  in Fig. 6. The V and B-V ranges are correlated and the values of V are more strongly variable at maximum light than at minimum light as in the case of other RR Lyrae stars with Blazhko effect.

Our photometric results are in good agreement with those obtained by Preston and Spinrad /Ap. J. 147, 1967/. Nevertheless there are some slight differences especially in the  $\delta_2$  values because accurate observations in U-B could not be made under the unsatisfactory observing conditions near Budapest.

Figures 7a and b show the amplitude variation  $\Delta A$  of the  $m / \psi /$  curves and the phase  $\psi$  of the maxima of the same curves plotted against  $\varphi$ .  $\Delta A$  have two maxima in each colour. The first of the maxima is at phase  $\varphi = 0,90$  on the ascending branch and the second one - which is higher, is at the phase of the light maximum /  $\varphi = 0,00$  /. It is evident from the figure that the light curves do not change significantly between the  $\varphi = 0,35 - 0,55$  phase interval during the Blazhko cycle. It is however, rather surprising that there is a very deep minimum at phase 0,94 on the ascending branch between the two maxima mentioned above. This deep minimum indicates that there exists a point on the ascending branch which does not show any significant oscillation during the Blazhko cycle while the ascending branch before and after it and especially the light maximum shows considerable oscillation. It is very interesting to compare our results with those obtained for AR Herculis by Almár /1961/. The same curves obtained for AR Her. also show double maxima but at other phases. The essential difference is that the first maximum of AR Her. is higher than the second one and the deep minimum is situated at the phase of light maximum.

Figure 5  
 The two-colour diagrams at different phases of the secondary period.  
 The dashed line represents the main sequence.

Figure 6  
 The curves show the typical variation of  $V_{max}$ ,  $V_{min}$ ,  $(B-V)_{max}$ ,  $(B-V)_{min}$  and  $\delta_2$  Preston index, during the secondary period.

Figure 7a shows the amplitudes of light curves belonging to different phases  $\phi$  of figures 3a and 3b.

Figure 7b  $\psi_{max}$  points show the  $\phi$  secondary phase of maxima of  $\phi$  phase curves in the figure 3.

Figure 8 The O-C secular variations of three magnitude levels of the ascending branch of the main period.

This may be connected with the behaviour of the double light maximum of AR Her which appears at certain phases of the secondary period while no double maximum can be observed for RV UMa. The most important theoretical consequence of the fact that there is no oscillation on a certain phase point of the ascending branch of RV UMa during the Blashko period suggests that the fundamental and the secondary period can not arise due to two beat periods. That is to say in the case of superposition of beat periods the ascending branch of the main period would need to oscillate to produce the required effect in each of its phase points during the Blashko period.

Figure 8 shows the /O-C/ secular variation of three magnitude levels of the ascending branch of the main period. The /O-C/ variations of the magnitude levels  $m:0,8$ ,  $0,5$ ,  $0,3$  are cyclic and coincident with each other. The length of the cycle is approximately 6-8 years. The cyclic variation of these fixed magnitude points of the ascending branch is due to the secular cyclic variation of the light curve form. When the /O-C/ is more positive, the rising branch of the light curve is always steeper during the secondary period and vice versa; the less positive the /O-C/ variation the more sinusoidal in form the light curve.

Whatever the cause of the cyclic variation of the light curve form, the length of this cyclic variation of RV UMa is commensurable with that of RR Lyrae. However, this length of cyclic variation corresponds to the magnitude of the magnetic solar cycle therefore the suspicion that the cyclic variation is a magnetic variation of the variable star, as suggested by Detre, seems reasonable.
