AC ANDROMEDAE

ABSTRACT

More than five thousand photographic observations of AC Andromedae made at the Konkoly Observatory between 1935 and 1956, as well as 680 photoelectric ones (obtained in the period 1954 - 1956) are published. The values of the three periods are refined.

INTRODUCTION

The variable star AC And (BD +47°4104, 9^m.4) was discovered by *Guthnick* and *Prager* (1927). The discoverers and the other observers, especially *Lause* (1932, 1933) were long at a loss for an explanation of its strong light curve variations. The light variation was sometimes definitely of RR Lyrae type, but in spite of the efforts made, no adequate period could be derived for the light changes. Ten years after the star's discovery, *Florja* (1937) made considerable progress in investigating its strange behaviour. He complemented the previously published observations with his own visual ones and on thoroughly investigating the light curves, he found that the course of the light variation could be described as the linear superposition of the light curves of two RR Lyrae type stars, one of which had a period of 0.525 day; the other having 0.711 day and a somewhat smaller amplitude. Subsequent observers also found that when the maxima of the 0.525 day and 0.711 day cycles coincided the observed maxima were high, otherwise they remained low or completely disappeared.

The strange behaviour of this star also aroused *L. Detre's* interest and in 1935 he included AC And into the observing programme of Konkoly Observatory. In 1941, the present author also took up the observations. Up to 1954, observations had been carried out photographically; numerous photoelectric observations were obtained between 1954 and 1956. The photoelectric observations made from 1958 through 1962 were analysed by *Fitch* and *Szeidl* (1976).

It was realized that *Florja's* periods could not explain the characteristics of the light curves in a satisfactory manner even though they could be used successfully to predict the times of the highest maxima. Relying

upon these findings it was suspected that, in order to account the strongly variable light curves, further period or periods should have been supposed over and above the well-known two periods (cf. *Guman*, paper read at the Variable Star Conference, Budapest, 27 August 1956, Mitt. Sternw. ung. Akad. Wiss. No. 42. 1957, p.3; *Kukarkin et al.*, 1969).

In their thorough analysis of the 1958-1962 observations *Fitch* and *Szeidl* (1976) showed that there was, indeed, a third period of 0.421 day in the pulsation of AC And. The complicated light variation can be adequately explained by the simultaneous, non-linearly coupled pulsations with these three periods.

Since AC And exhibits this unique phenomenon, every observation even if less accurate than photoelectric ones may be of importance, hence the presentation of my unpublished observations. The use of these data have enabled more accurate values of the periods to be determined.

THE OBSERVATIONS

The observations published here were carried out between 1935 and 1956 and include 5670 photographic observations in the years 1935-1954, and 680 photoelectric observations in the period 1954-1956.

The photographic observations were commenced by Drs. *Julia Balázs* and *L. Detre* who obtained 184 observations on five nights in 1935-1937. Between 1941 and 1954 the present author made 4138 observations during 133 nights; the remaining observations were collected by the staff with the 7 inch astrograph of Konkoly Observatory. First Eastman 40, later Guilleminot Superfulgur photographic plates were used. Usually 20-25 four-minute exposures were taken in succession on each plate. The measurements of all the plates and the reductions were carried out by the author. Most of the plates were measured by a Rosenberg-type electromicrophotometer, only a few by a Zeiss-type Schnell-photometer.

The photographic magnitudes of the comparison stars (Table I) have been determined by comparison with NPS utilizing two plates made in 1935 and 1949. The identification chart of the comparison stars is given in Figure 1. The heliocentric Julian Dates and the obtained photographic magnitudes of AC And are presented in Table II.

The photoelectric observations were made on Konkoly Observatory's 24 inch reflector without any filter; the photometer employed an uncooled RCA 1P21 photomultiplier (for detailed description see *Balázs and Detre*, 1954).

BD +48°3989 (=c of the photographic sequence) served as the comparison star. The photoelectric observations (in the sense variable minus comparison) can be found in Table III.

THE PERIODS

As has been already mentioned, according to Fitch and Szeidl (1976), AC And is a short period cepheid in which the fundamental, first and sec-

ond overtone pulsation modes are simultaneously excited and non-linearly coupled. Since the photoelectric observations used in their work cover only a short time interval (1958-1962) they accepted the two known periods derived earlier by me (see Kukarkin et al., 1969) and could determine the third period only with less accuracy. Therefore it seemed desirable to use the photographic observations covering nearly 20 years for a more accurate determination of the periods. (The photoelectric observations are due to be discussed in a future paper.)

The photographic observational material given here is the most extensive ever published of this star; in particular, the observations between 1945 and 1953 provide a homogeneous continual series.

To facilitate the processing of the data and light curves it seemed reasonable to make more characteristic sets of brightness variation but a smaller number. Thus all the photographic observations were collected on a magnetic tape and then plotted thereby enabling the light curves to be used with sufficient certainty (neglecting the possible microstructure). Then, from the light curves obtained in such a way, the magnitudes could be read in by a digitizer to a magnetic tape at equidistant time intervals. (The length of the intervals depended on the character of the light curves: for low maxima the interval was chosen to be 0.02^d or 0.01^d , for high maxima it was 0.005^d .) All the manipulations were carried out by an HP 9810A computer. The homogeneous sets of 1688 magnitudes obtained by the above described procedure are given in Table IV. These data sets well represent the light variations of AC And.

It is intended that the shape of the light curves and its variations be discussed in a later paper. Here, it is mentioned that the height of maxima changes considerably depending on the phase relations of the three periods. The highest maxima reach the value of 10.20 magn., the lowest ones are at 11.30 magn. The amplitude belonging to the highest maxima exceeds 1.5 magn., the smallest amplitude is hardly more than 0.2 magn. (see Figure 2).

In order to obtain more accurate values of the periods the following procedure was used. If all the observations are plotted against phases of one of the three periods the mass of points near 0 phase shows all the maxima according to the period in question, from the lowest ones to the highest ones. About half a period later, because of the minima at given period, the points are under the highest maxima. The maximum of the envelope of the mass of points determines the 0 phase of the period in question very accurately.

The periods given in the paper of Fitch and Szeidl (1976) were used in

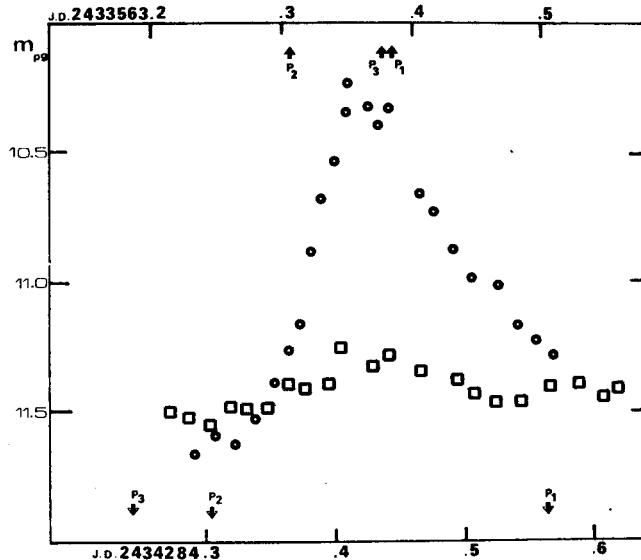

Figure 2

One of the brightest (J.D. 2433563 open circles) and one of the faintest (J.D. 2434284 squares) maxima of AC And. The arrows indicate the calculated zero phases for each of the three periods. Each point is a mean of three photographic observations on the ascending branch, otherwise of five observations.

the construction of the figures - supposing that at one of the highest maxima (on J.D. 2432467) the phase of each period was nearly 0. These initial elements were:

$$\text{J.D. } 2432467.373 + 0.71124243 \cdot E_1$$

Guman (see Kukarkin et al., 1969)

$$\text{J.D. } 2432467.373 + 0.52512677 \cdot E_2$$

$$\text{J.D. } 2432467.373 + 0.421069 \cdot E_3$$

Fitch and Szeidl (1976)

All the utilized observations of the phases of these periods showed considerable scattering. Even so, it is apparent from the figures that the envelope curves slowly shifted from year to year. Therefore the observations were divided into ten groups and then separately plotted against the phase of each of the three periods. In this way ten separate envelopes could be constructed for each period. The shift of each envelope determined an O-C value and, finally ten O-C residuals could be derived for each period. Using these data a least squares solution gave the following elements:

$$\text{J.D. } 2428009.429 + 0.71122470 \cdot E_1 \\ \pm .005 \quad \pm .00000074$$

$$\text{J.D. } 2428009.571 + 0.52512629 \cdot E_2 \\ \pm .004 \quad \pm .00000045$$

$$\text{J.D. } 2428009.496 + 0.42106751 \cdot E_3 \\ \pm .004 \quad \pm .00000037$$

With the phases deduced from these new elements all the observations were plotted for each period separately (Figure 3a, 3b and 3c). Most of the points of the different epochs coincided in a satisfactory manner. It is immediately evident that the 0.711 and 0.525 periods have a much greater influence on the light curve than the 0.421 period. The amplitude of the envelopes belonging to the longer periods is about 1.0 magn; the faintest observations are about 0.3 magn. brighter at phase $\phi = 0.2$ than at $\phi = 0.6$. The envelope curve drawn according to the 0.421 period has an amplitude of only 0.8 magn. with scattering of the observations greater in the direction of the phase axis, and finally the influence of the period cannot be seen at the faintest observations.

Knowing the three periods it is worth examining the length of cycles which repeat the same types of light curves. From the periods two different cycles can be derived which yield the repetition of the highest maxima. One of them is:

$$3P_1 = 2.134, 4P_2 = 2.101, 5P_3 = 2.105$$

which was already found by the very first observers. This 2.1^d repetition disappears very quickly, only two or three repetitions can be followed.

The other cycle is :

$$45P_1 = 32.005, 61P_2 = 32.033, 76P_3 = 32.001$$

which can be observed two or three times one after the other during an observational season. Azarnova (1956, 1957) considered this 32^d cycle as the period of the light curve changes, like the period of the Blazhko effect in RR Lyrae stars. But two features contradict this suggestion. First this period cannot be followed after two or three repetitions and, secondly, the height of maxima does not change continuously during such a cycle.

Besides these two cycles, no other coincidences of this kind between the periods could be found. Both of these cycles are nearly integral multiples of one day and, in consequence, if the star is observed only from one geographical location spurious secular variations of the light curve may be

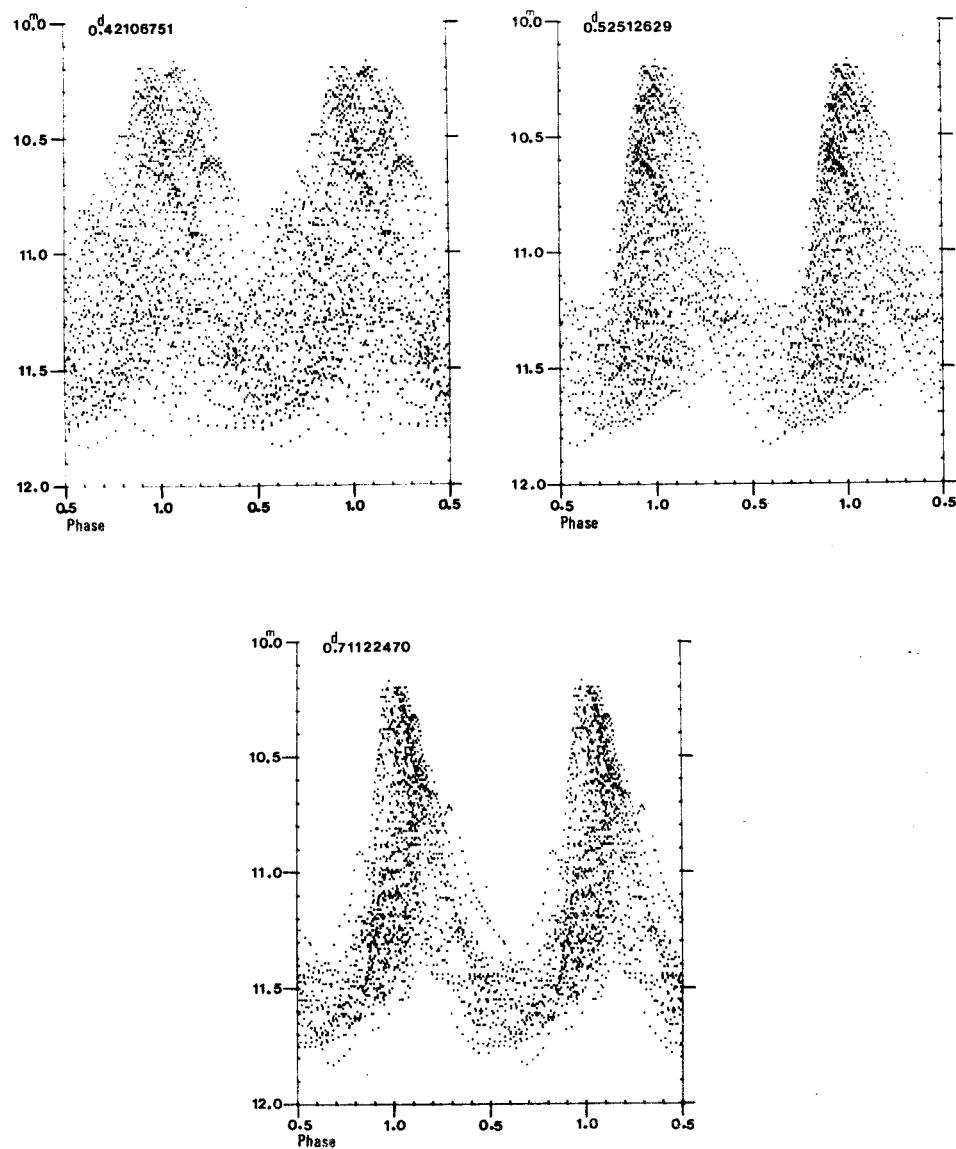

Figure 2a, b, c

Characteristic points of the light curves plotted against phases of each of the three periods

deduced because there are observational seasons during which no very high maxima can be observed.

From the above data it is not possible to decide which of the two longer periods has the greater influence on the light curve though Fitch and Szeidl's (1976) results suggest that it is the 0.711^d period.

The photographic material presented indicates that the considerable secondary and double maxima on the light curves calculated by Florja and his followers are not real, even the smaller waves required by Fitch and Szeidl's calculated light curves (see the light curve on J.D. 2437562 in their Figure 1) cannot be seen on the observed light curves. Nevertheless smaller waves can really be found on the light curves, especially near the minimum and maximum. But these waves do not seem to be related to the known periods. These are rather like the phenomena observed on some light curves of RR Lyrae type stars (e.g. RR Lyrae itself). The observations indicate that one can observe three 0.7^d cycles during 2.1^d that are strongly deformed by the other periods, but no significant secondary maxima are recognizable. This would refer to the fact that the 0.711^d period is the fundamental one. This problem could be, however, investigated by international (literally intercontinental) cooperation given a some days' long continuous light curve.

The author wishes to express his thanks to Prof. I. Almár, the director of the Cosmic Geodesic Observatory, for allocation of computer time.

Budapest-Szabadsághegy, 31 August 1981
